

Control of Very Low Pressure Gases in Industrial and Laboratory Processes

Most engineers are comfortable working with pressures above 1 psig (69 mbar), but are often confused about the best way to control much lower pressures, typically expressed in inches of water column (1 psig = 27.7 inH₂O). There are dozens of industrial applications for low and ultra low pressure. Some common examples are:

- Tank nitrogen padding or blanketing
- Product integrity testing
- Glove boxes
- Fuel burner systems
- Tubing die extrusion control

While specific product solutions have been developed to address the common applications listed above, it can be confusing for the engineer or scientist to know how best to address their special application requirements. For example, their pressure range, flow rate, accuracy requirements, or automation require-

ments make it difficult to select the right control approach.

This article describes several traditional and emerging pressure control methods in this low pressure range, both manual and computer automated. For the purposes of this article, we can define "low pressure" as being below 1 psig (69 mbar) and ultra low pressure as being below 0.1 psig (3 inH₂O, 7 mbar).

Low pressures can be conveniently measured by digital manometers, such as this economical Extech HD700. It has a range of 0 to 52 inH₂O (129 mbar) and resolution of 0.01 inH₂O (0.02 mbar).

Precision Air Regulators Applications: Instrumentation & actuation

There are numerous precision air regulators targeted at instrumentation applications in the range of 1/8" or 1/4". Several of these can control pressures below 1 psig (69mbar), though no commonly available solutions are precise in the ultra low range. These regulators typically are self-relieving, meaning that they can vent downstream air when the set-point is lowered or if the downstream

This Bellofram Type 10 is a two-stage servo air pressure regulator that offers very high performance for pressures down to 0.5 psi (34 mbar).

pressure exceeds the set-point. In addition, most of these have a slight "consumption" or weep of air, which gives them more precision and stability.

Dual stage servo pressure regulators have set a gold standard in terms of small air regulator precision in the range down to 0.5 psig (35 mbar). These regulators utilize a dual stage servo mechanism to virtually eliminate droop with varying flow rates. They are available in ranges from 0.5 to 25 psig (35 to 1724 mbar), and up to 120 psig (8.3 bar). Unfortunately, the stainless steel capsule used in these designs do not allow for any set-point below 0.5 psig, limiting the usefulness of this precision device in these applications.

Jeff Jennings, P.E., is founder and president of Equilibar, LLC, a provider of high precision pressure control solutions. Prior to Equilibar, he worked as a process development engineer for 23 years. He is a licensed professional engineer in North Carolina and holds several patents. Mr. Jennings can be reached at jeff.jennings@equilibar.com or 828-650-6590.

Droop: the decrease in output pressure from a pressure reducing regulator due to increasing flow rate.

Simpler single stage regulators can easily control pressure down to 0 psig for short term applications. These commonly come in pressure ranges as low as 0 to 2 psig (138 mbar). Because of their extreme sensitivity, they can be used short-term pressure settings down to the range of 0.25 inH₂O (.6 mbar). However, our experience shows that these regulators have limited long-term stability at pressures below 6 inH₂O (15 mbar). Settings below 3 inH₂O (7 mbar) are definitely not practical for long duration due to drift.

It is a good idea to maintain filter regulators upstream of any precision air regulator, to provide stable inlet pressures and to remove moisture and particulate. Single stage regulators are especially dependent on stable inlet pressures for good performance.

High Flow/Low Pressure Regulators

Applications: Tank Blanketing Regulators

At the high flow end of the spectrum, control valves are often outfitted with pilot-actuated feedback systems to provide control at pressures down to 0.25 in H₂O. These systems can be quite complex and involve up to three separate regulating mechanisms. While this solution is desirable for the many large tank blanketing systems, the size and complexity would be prohibitive for most lower-flow applications. Single stage tank blanketing regulators are simpler and more suitable for

smaller installations, and are available in smaller sizes such as 1" and ½". These single stage regulators can control down to 2 inH₂O (5 mbar) with excellent sensitivity.

Single stage 1" tank blanketing regulators, like those from the Swagelok® RHPS series, offer high precision control for smaller installations.

A typical single-stage fuel gas regulator, sold by Marsh Bellofram's Belgas division, controls down to 3 inH₂O (7 mbar).

Propane & Natural Gas Regulators

The propane and natural gas industries have developed a simpler form of pressure reducing regulator that functions down to about 3 inH₂O (7 mbar). Single stage regulators such as the one shown at right use relatively large rubber diaphragms to generate enough actuating forces to control in these low pressure ranges. Often a lever arm is used to magnify the forces from the diaphragm to provide adequate force to control the inlet valve. These fuel regulators are available in sizes ¼" and larger.

Electronic Pressure Regulators

Electronic pressure regulators, often called electro-pneumatic regulators (EPR's), control pressure by adjusting valves in response to a pressure sensor. One very common form of EPR is the servo electronic pressure regulator. A major advantage to the servo EPR is that it can be used for both low pressure and ultra low pressure applications (down to 0 to 4 inH₂O [10 mbar]) just as easily as the more common industrial pressure ranges such as 3-15 psig, 0-100 psig, etc) (207 to 1034 mbar and 0 to 7 bar).

Servo electronic pressure regulators work by using a push valve and a vent valve to maintain the outlet pressure at the desired set-point. A small internal pressure sensor monitors the output pressure and a digital or analog controller adjusts the timing of the servo valves to maintain the pressure very near set-point.

These EPRs typically require a DC power supply and a set-point signal. Analog controllers typically accept either current (4-20 mA) or voltage (typically 0-10 or 0-5 VDC) input. Models with digital circuits can accept serial communications (such as RS-232 or Ethernet) in addition to the common analog standards. Most models also offer a feedback signal reporting on the pressure sensor value.

Proportion-Air's innovative QPV electronic pressure regulator is available in pressure ranges down to 0 to 4 inH₂O (0-10 mbar) with resolutions as high as 0.005% full scale.

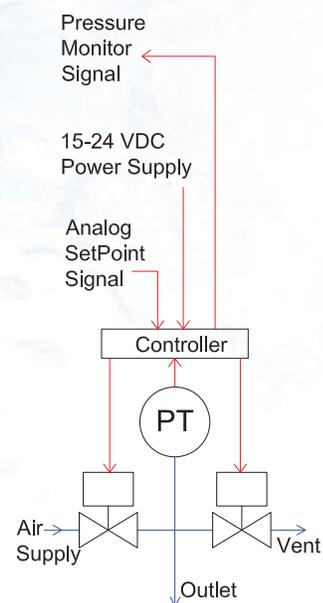

Specialized Systems for Extrusion Control

Specialized systems have been developed to provide low pressure control specifically for tubing extrusion systems. These systems utilize sensitive spring regulators, but also have the ability to include close-loop feedback control and electronic set-point automation. Commonly available systems control pressure down to 0-2 inH₂O (0 – 5 mbar) range, with flow rates up to 5 SCFH (2.4 SLPM).

Most EPR manufacturers also offer a "two loop" option with accepts an external sensor input and controls the output pressure to resolve the external sensor to the desired set-point value.

One advantage of the servo EPR is that it can theoretically operate down to the lowest pressure range of available pressure transmitters. Several industrial EPR manufacturers offer standard models down to 0-1 psig (0- 69 mbar) range, and claim accuracies in the range of 0.5% full scale. A few manufacturers offer full scale ranges down to 0-10 inH₂O (0-25 mbar) and even 0-4 inH₂O (0-10 mbar) .

One disadvantage of the servo EPR is that the binary valve action can result in jittery or uneven pressure output if not tuned carefully to the system dynamics. An improved hybrid EPR design has recently been developed that allows the push valve to partially open. By combining this analog push valve action with a small bleed, these innovative EPRs are able to provide incredible resolution (as high as 0.005%), quietness and stability to its ultra low pressure control.

Servo electronic pressure regulators function by cycling both "push" and "vent" valves to maintain the target outlet pressure as measured by an internal pressure sensor.

MicroAir extrusion control system by Online Controls can control pressures down to 2 inH₂O.

Calibration-Class Pressure Controllers

Not surprisingly, the highest precision and stability in pressure control is marketed for calibration applications.

These calibrators typically sell in the range of \$3000 to \$10,000 and offer very high sensitivity and stability by controlling pressure in response to high-end pressure transmitters. This class of controllers is intended for very low flow rates (static or nearly so). These devices boast precision as high as 0.005% Reading + 0.005% FS and can auto-range to pressures as low as 0-10 inH₂O (0-25 mbar).

GE Sensing's PACE 6000 automated pressure controller has available ranges down to 0-10 inH₂O (0-25 mbar).

Dome-Loaded Pressure Regulators

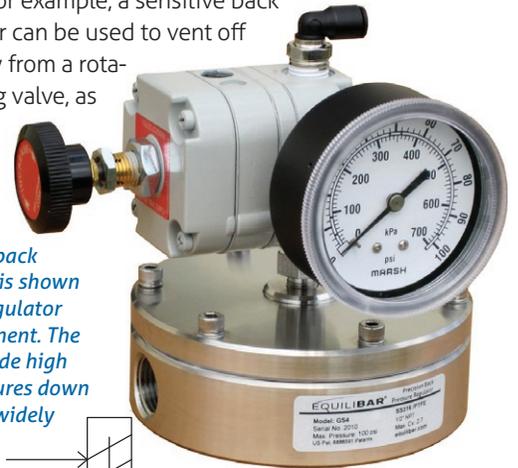

While the precision air regulators and electronic pressure regulators above are able to economically provide for very low pressure control, they are both limited in maximum flow rate. A dome-loaded pressure regulator is often used as a type of flow amplifier, taking the precision signal from the smaller regulator, and relaying it into a larger process stream. This can be done with either open-loop or closed loop control (where a PID controller adjusts the signal pressure in response to the error sensed by a process pressure transmitter).

Another major reason to use a dome-loaded pressure regulator is to achieve chemical isolation between a process stream and the signal instruments. For example, a flammable or corrosive gas stream is not typically suitable for use with precision pressure regulators or electronic pressure regulators. A dome-loaded regulator can be used to separate the "clean" instruments from the "dirty" process.

While there are few if any pressure reducing dome-loaded regulators suitable for the ultra low pressure range, a new ultra sensitive back pressure regulator can provide excellent control down to the 0.5 inH₂O (1 mbar) range. These devices are sensitive to changes as small as 0.01 inH₂O (0.02 mbar).

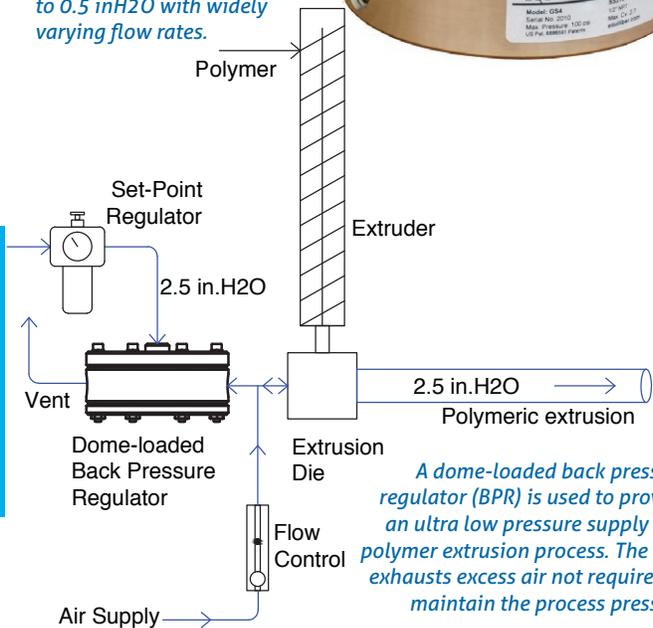

While most users think in terms of pressure reducing regulators, many applications can be reconfigured to take advantage of the ultra sensitivity available from these dome-loaded back pressure regulators. For example, a sensitive back pressure regulator can be used to vent off excess gas supply from a rotameter or metering valve, as in the example illustrated below.

The ½" Equilibar® GS4 dome-loaded back pressure regulator is shown with a set-point regulator for manual adjustment. The Equilibar can provide high precision for pressures down to 0.5 inH₂O with widely varying flow rates.

Pressure Reducing Regulators control the downstream pressure by opening up to increase pressure

Back Pressure Regulators control the upstream pressure by opening up to reduce pressure

A dome-loaded back pressure regulator (BPR) is used to provide an ultra low pressure supply to a polymer extrusion process. The BPR exhausts excess air not required to maintain the process pressure
